# CS178 Homework 1

## Due: Monday, October 7th 2024 (11:59 PM)

---

## Instructions

Welcome to CS 178!

This homework (and many subsequent ones) will involve data analysis and reporting on methods and results using Python code. You will submit a **single PDF file** that contains everything to Gradescope. This includes any text you wish to include to describe your results, the complete code snippets of how you attempted each problem, any figures that were generated, and scans of any work on paper that you wish to include. It is important that you include enough detail that we know how you solved the problem, since otherwise we will be unable to grade it.

Your homeworks will be given to you as Jupyter notebooks containing the problem descriptions and some template code that will help you get started. You are encouraged to modify these starter Jupyter notebooks to complete your assignment and to write your report. You may add additional cells (containing either code or text) as needed. This will help you not only ensure that all of the code for the solutions is included, but also will provide an easy way to export your results to a PDF file (for example, doing *print preview* and *printing to pdf*). I recommend liberal use of Markdown cells to create headers for each problem and sub-problem, explaining your implementation/answers, and including any mathematical equations. For parts of the homework you do on paper, scan it in such that it is legible (there are a number of free Android/iOS scanning apps, if you do not have access to a scanner), and include it as an image in the Jupyter notebook.

Several problems in this assignment require you to create plots. Use `matplotlib.pyplot` to do this, which is already imported for you as `plt`. Do not use any other plotting libraries, such as `pandas` or `seaborn`. Unless you are told otherwise, you should call `pyplot` plotting functions with their default arguments.

If you have any questions/concerns about the homework problems or using Jupyter notebooks, ask us on EdD. If you decide not to use Jupyter notebooks, but go with Microsoft Word or Latex to create your PDF file, make sure that all of the answers can be generated from the code snippets included in the document.

### Summary of Assignment: 100 total points

- Problem 1: Exploring a NYC Housing Dataset (30 points)
  - Problem 1.1: Numpy Arrays (5 points)
  - Problem 1.2: Feature Statistics (5 points)
  - Problem 1.3: Logical Indexing (5 points)
  - Problem 1.4: Histograms (5 points)
  - Problem 1.5: Scatter Plots (10 points)
- Problem 2: Building a Nearest Centroid Classifier (50 points)
  - Problem 2.1: Implementing Nearest Centroids (30 points)
  - Problem 2.2: Evaluating Nearest Centroids (20 points)
- Problem 3: Decision Boundaries (15 points)
  - Problem 3.1: Visualize 2D Centroid Classifier (5 points)
  - Problem 3.2: Visualize 2D Gaussian Bayes Classifier (5 points)
  - Problem 3.3: Analysis (5 points)
- Statement of Collaboration (5 points)

Before we get started, let's import some libraries that you will make use of in this assignment. Make sure that you run the code cell below in order to import these libraries.

**Important: In the code block below, we set `seed=123`. This is to ensure your code has reproducible results and is important for grading. Do not change this. If you are not using the provided Jupyter notebook, make sure to also set the random seed as below.**

In [1]:
```
# If you haven't installed numpy, pyplot, scikit, etc., do so:
!pip install -U scikit-learn
```

```

from io import StringIO

# Fix the random seed for reproducibility
# !! Important !! : do not change this
seed = 123
np.random.seed(seed)
```

---

# Problem 1: Exploring a NYC Housing Dataset

In this problem, you will explore some basic data manipulation and visualizations with a small dataset of real estate prices from NYC. For every datapoint, we are given several real-valued features which will be used to predict the target variable, y, representing in which borough the property is located. Let's first load in the dataset by running the code cell below:

In [3]:
```python
# Load the features and labels from an online text file
url = 'https://ics.uci.edu/~ihler/classes/cs178/data/nyc_housing.txt'
with requests.get(url) as link:
    datafile = StringIO(link.text)
    nych = np.genfromtxt(datafile,delimiter=',')
    nych_X, nych_y = nych[:,:-1], nych[:,-1]
```

These data correspond to (a small subset of) property sales in New York in 2014. The target, $y$, represents the borough in which the property was located (0: Manhattan; 1: Bronx; 2: Staten Island). The observed features correspond to the property size (square feet), price (USD), and year built; the first two features have been log2-transformed (e.g., $x_1 = \log_2(\text{size})$) for convenience.

## Problem 1.1 (5 points): Numpy Arrays

The variable `nych_X` is a numpy array containing the feature vectors in our dataset, and `nych_y` is a numpy array containing the corresponding labels.

- What is the shape of `nych_X` and `nych_y` ? (Hint)
- How many datapoints are in our dataset, and how many features does each datapoint have?
- How many different classes (i.e. labels) are there?
- Print rows 3, 4, 5, and 6 of the feature matrix and their corresponding labels. Since Python is zero-indexed, we will count our rows starting at zero -- for example, by "row 0" we mean `nych_X[0, :]` , and "row 1" means `nych_X[1, :]` , etc. (Hint: you can do this in two lines of code with slicing).

In [8]:
```python
import numpy as np
import requests
from io import StringIO

url = 'https://ics.uci.edu/~ihler/classes/cs178/data/nyc_housing.txt'
with requests.get(url) as link:
    datafile = StringIO(link.text)
    nych = np.genfromtxt(datafile, delimiter=',')
    nych_X, nych_y = nych[:, :-1], nych[:, -1]

#- What is the shape of `nych_X` and `nych_y`?
shape_X = nych_X.shape
shape_y = nych_y.shape

#- How many datapoints are in our dataset, and how many features does each datapoint have?
num_data_points = shape_X[0]
num_features = shape_X[1]

#- How many different classes (i.e. labels)  are there?
unique_labels = np.unique(nych_y)
num_classes = len(unique_labels)
```

```
#print results
print(f"Shape of nych_X: {shape_X}")
print(f"Shape of nych_y: {shape_y}")
print(f"Number of data points: {num_data_points}")
print(f"Number of features per data point: {num_features}")
print(f"Unique classes (labels): {unique_labels}")
print(f"Number of classes: {num_classes}")
```

```
Shape of nych_X: (300, 3)
Shape of nych_y: (300,)
Number of data points: 300
Number of features per data point: 3
Unique classes (labels): [0. 1. 2.]
Number of classes: 3
```

In [11]:
```
for features, label in zip(nych_X[3:7, :], nych_y[3:7]):
    print(f"Features: {features}, Label: {label}")
```

```
Features: [  11.839204   19.416995 1980.      ], Label: 2.0
Features: [  18.517396   25.357833 1973.      ], Label: 1.0
Features: [  11.050529   19.041723 2014.      ], Label: 2.0
Features: [  17.255803   26.280297 1917.      ], Label: 0.0
```

## Problem 1.2 (5 points): Feature Statistics

Let's compute some statistics about our features. You are allowed to use `numpy` to help you with this problem -- for example, you might find some of the `numpy` functions listed here or here useful.

- Compute the mean, variance, and standard deviation of each feature.
- Compute the minimum and maximum value for each feature.

Make sure to print out each of these values, and indicate clearly which value corresponds to which computation.

In [7]:
```
# Calculate the mean of each feature
mean_values = np.mean(nych_X, axis=0)
print("Mean of each feature:", mean_values)

# Calculate the variance of each feature
variance_values = np.var(nych_X, axis=0)
print("Variance of each feature:", variance_values)

# Calculate the standard deviation of each feature
std_dev_values = np.std(nych_X, axis=0)
print("Standard Deviation of each feature:", std_dev_values)

# Calculate the minimum value of each feature
min_values = np.min(nych_X, axis=0)
print("Minimum value of each feature:", min_values)

# Calculate the maximum value of each feature
max_values = np.max(nych_X, axis=0)
print("Maximum value of each feature:", max_values)
```

```
Mean of each feature: [  14.11839247   21.90711615 1946.35333333]
Variance of each feature: [   6.60022492    8.87193012 1253.08182222]
Standard Deviation of each feature: [ 2.56909029  2.97857854 35.39889578]
Minimum value of each feature: [  10.366322   16.872675 1893.      ]
Maximum value of each feature: [  20.152714   29.123861 2014.      ]
```

## Problem 1.3 (5 points): Logical Indexing

Use numpy's logical (boolean) indexing to extract only those data corresponding to $y = 0$ (Manhattan). Then, compute the mean and standard deviation of *only these* data points. Then, do the same for $y = 1$ (Bronx).

Again, print out each of these vectors and indicate clearly which value corresponds to which computation.

In [8]:
```
# Problem 1.3
# Extract data for Manhattan (y = 0)
manhattan_data = nych_X[nych_y == 0]

# Compute the mean and standard deviation for Manhattan
manhattan_mean = np.mean(manhattan_data, axis=0)
manhattan_std = np.std(manhattan_data, axis=0)

# Print Manhattan statistics
print("Manhattan (y=0) mean of each feature:", manhattan_mean)
print("Manhattan (y=0) standard deviation of each feature:", manhattan_std)

# Extract data for Bronx (y = 1)
bronx_data = nych_X[nych_y == 1]

# Compute the mean and standard deviation for Bronx
bronx_mean = np.mean(bronx_data, axis=0)
bronx_std = np.std(bronx_data, axis=0)

# Print Bronx statistics
```

```
print("Bronx (y=1) mean of each feature:", bronx_mean)
print("Bronx (y=1) standard deviation of each feature:", bronx_std)
```

```
Manhattan (y=0) mean of each feature: [  16.1489863    25.07251963 1926.94      ]
Manhattan (y=0) standard deviation of each feature: [ 2.19416051  2.09812353 28.14562843]
Bronx (y=1) mean of each feature: [  14.60837771   21.4446885  1935.29      ]
Bronx (y=1) standard deviation of each feature: [ 1.89678446  1.99063026 22.96619037]
```

## Problem 1.4 (5 points): Feature Histograms

Now, you will visualize the distribution of each feature with histograms. Use `matplotlib.pyplot` to do this, which is already imported for you as `plt`. Do not use any other plotting libraries, such as `pandas` or `seaborn`.

- For every feature in `nych_X`, plot a histogram of the values of the feature. Your plot should consist of a grid of subplots with 1 row and 3 columns.
- Include a title above each subplot to indicate which feature we are plotting. For example, you can call the first feature "Feature 0", the second feature "Feature 1", etc.

Some starter code is provided for you below. (Hint: `axes[0].hist(...)` will create a histogram in the first subplot.)

In [11]:
```
import numpy as np
import requests
import matplotlib.pyplot as plt
from io import StringIO

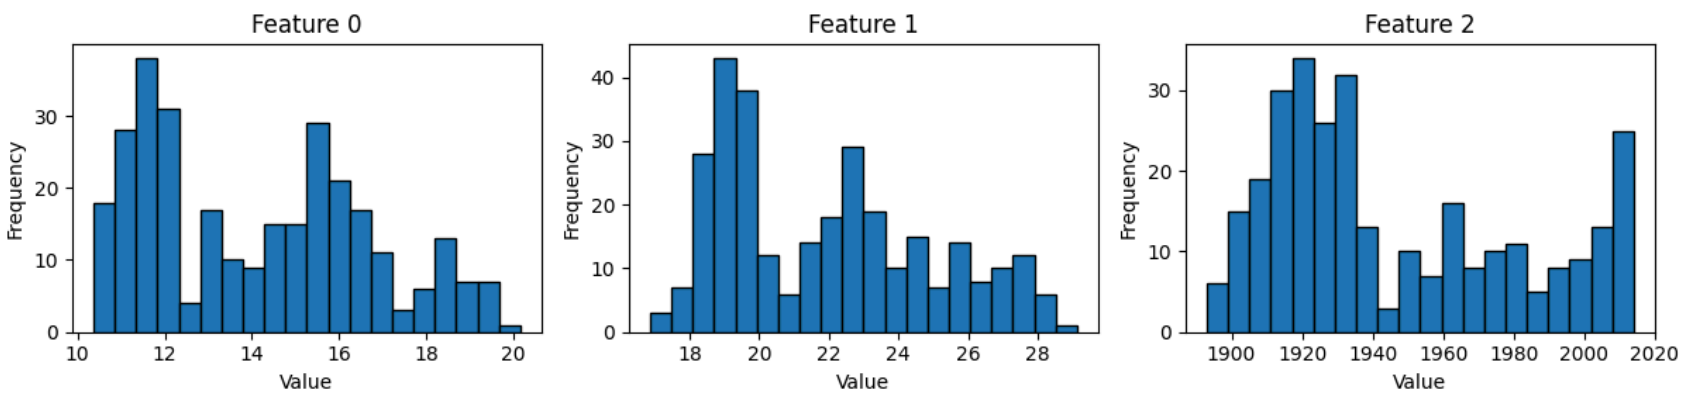
url = 'https://ics.uci.edu/~ihler/classes/cs178/data/nyc_housing.txt'
with requests.get(url) as link:
    datafile = StringIO(link.text)
    nych = np.genfromtxt(datafile, delimiter=',')
    nych_X, nych_y = nych[:, :-1], nych[:, -1]

# Problem 1.4
# Create a figure with 1 row and 3 columns
fig, axes = plt.subplots(1, 3, figsize=(12, 3))

# Plot histogram for each feature
for i in range(3):
    axes[i].hist(nych_X[:, i], bins=20, edgecolor='black')
    axes[i].set_title(f"Feature {i}")
    axes[i].set_xlabel("Value")
    axes[i].set_ylabel("Frequency")

# Adjust layout to prevent overlap
fig.tight_layout()

# Show the plot
plt.show()
```



## Problem 1.5 (10 points): Feature Scatter Plots

To help further visualize the NYC-Housing datset, you will now create several scatter plots of the features. Use `matplotlib.pyplot` to do this, which is already imported for you as `plt`. Do not use any other plotting libraries, such as `pandas` or `seaborn`.

- For every pair of features in `nych_X`, plot a scatter plot of the feature values, colored according to their labels. For example, plot all data points with $y = 0$ as blue, $y = 1$ as green, etc. Your plot should be a grid of subplots with 3 rows and 3 columns. (Hint: `axes[0, 0].scatter(...)` will create a scatter plot in the first column and first row).
- Include an x-label and a y-label on each subplot to indicate which features we are plotting. For example, you can call the first feature "Feature 0", the second feature "Feature 1", etc. (Hint: `axes[0, 0].set_xlabel(...)` might help you with the first subplot.)

Some starter code is provided for you below.

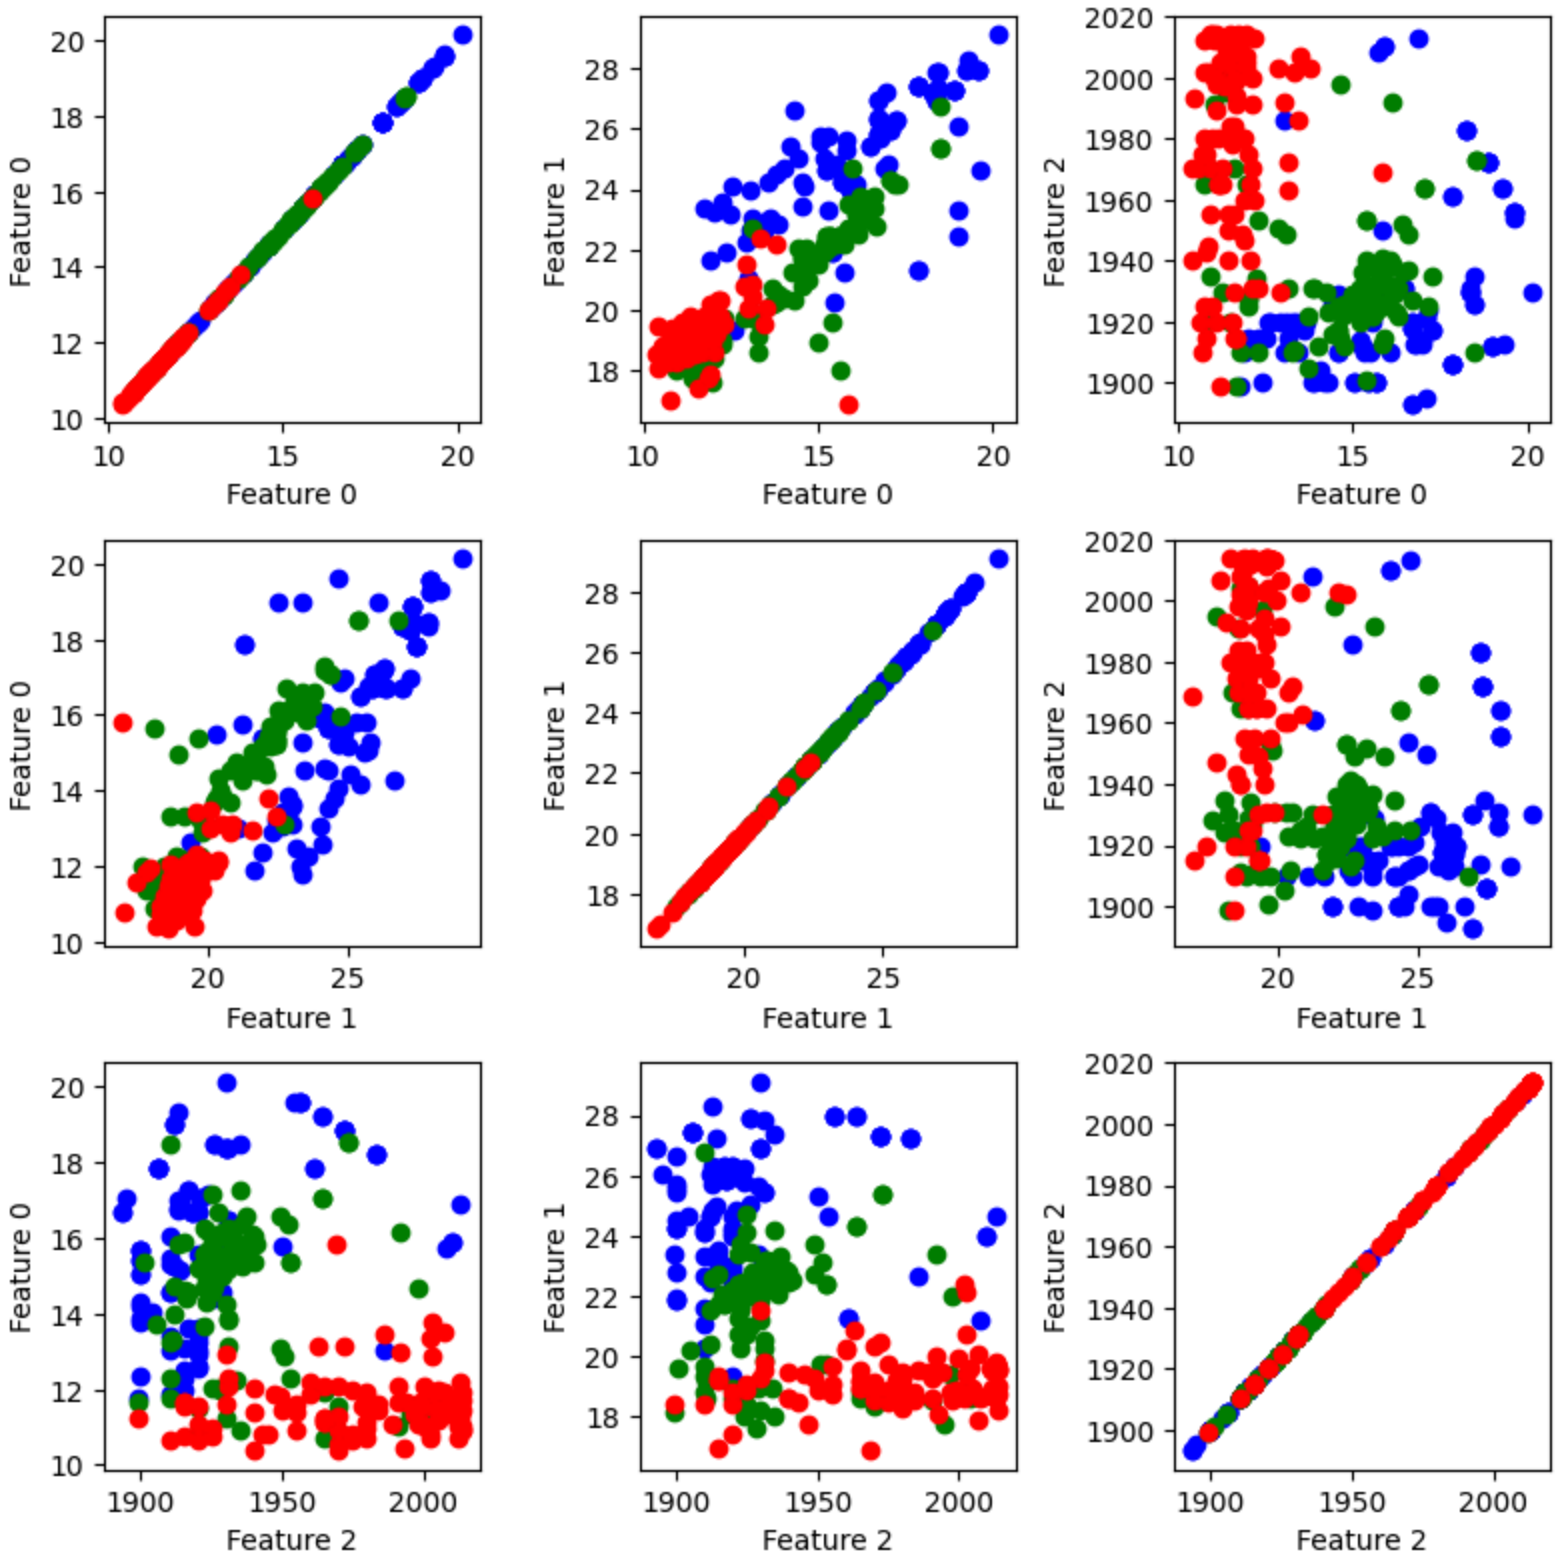
In [25]:
```
# Create a figure with 3 rows and 3 columns
fig, axes = plt.subplots(3, 3, figsize=(8, 8))

### YOUR CODE STARTS HERE ###
colors = ['blue', 'green', 'red']
```

```
# Loop through each pair of features and create a scatter plot
for i in range(len(axes)):
    for j in range(len(axes[i])):
        for c in np.unique(nych_y):
            axes[i,j].scatter(nych_X[nych_y==c,i], nych_X[nych_y==c,j] , color=colors[int(c)] )
        axes[i, j].set_xlabel(f"Feature {i}")
        axes[i, j].set_ylabel(f"Feature {j}")

###  YOUR CODE ENDS HERE  ###

fig.tight_layout()
```



---

# Problem 2: Nearest Centroid Classifiers

In this problem, you will implement a nearest centroid classifier and train it on the NYC data.

## Problem 2.1 (30 points): Implementing a Nearest Centroid Classifier

In the code given below, we define the class `NearestCentroidClassifier` which has an unfinished implementation of a nearest centroid classifier. For this problem, you will complete this implementation. Your nearest centroid classifier will use the Euclidean distance, which is defined for two feature vectors $x$ and $x'$ as

$$d_E(x, x') = \sqrt{\sum_{j=1}^{d} (x_j - x'_j)^2}.$$

- Implement the method `fit`, which takes in an array of features `X` and an array of labels `y` and trains our classifier. You should store your computed centroids in the list `self.centroids`, and their $y$ values in `self.classes_` (whose name is chosen to match `sklearn` conventions).
- Test your implementation of `fit` by training a `NearestCentroidClassifier` on the NYC data, and printing out the list of centroids. (These should match the means in Problem 1.3.)

- Implement the method `predict`, which takes in an array of feature vectors `X` and predicts their class labels based on the centroids you computed in the method `fit`.
- Print the predicted labels (using your `predict` function) and the true labels for the first ten data points in the NYCH dataset. Make sure to indicate which are the predicted labels and which are the true labels.

You are allowed to modify the given code as necessary to complete the problem, e.g. you may create helper functions.

In [61]:
```
class NearestCentroidClassifier:
    def __init__(self):
        # A list containing the centroids; to be filled in with the fit method.
        self.centroids = []

    def fit(self, X, y):
        """ Fits the nearest centroid classifier with training features X and training labels y.

        X: array of training features; shape (m,n), where m is the number of datapoints,
            and n is the number of features.
        y: array training labels; shape (m, ), where m is the number of datapoints.

        """
        # First, identify what possible classes exist in the training data set:
        self.classes_ = np.unique(y)

        # For each class, compute its centroid (mean vector of all points in that class)
        for c in self.classes_:
            # Extract data points corresponding to class c
            class_data = X[y == c]
            # Compute the mean of the class data (this is the centroid)
            centroid = np.mean(class_data, axis=0)
            # Append the centroid to the list of centroids
            self.centroids.append(centroid)

    def predict(self, X):
        """ Makes predictions with the nearest centroid classifier on the features in X.

        X: array of features; shape (m,n), where m is the number of datapoints,
            and n is the number of features.

        Returns:
        y_pred: a numpy array of predicted labels; shape (m, ), where m is the number of datapoints.
        """
        # List to store predicted labels
        y_pred = []

        # Iterate over each test point in X
        for x in X:
            # Calculate the Euclidean distance from x to each centroid
            distances = [np.linalg.norm(x - centroid) for centroid in self.centroids]
            # Find the index of the nearest centroid
            nearest_centroid_index = np.argmin(distances)
            # Append the corresponding class (self.classes_[nearest_centroid_index]) to y_pred
            y_pred.append(self.classes_[nearest_centroid_index])

        # Convert the predictions to a numpy array and return
        return np.array(y_pred)
```

Here is some code illustrating how to use your `NearestCentroidClassifier`. You can run this code to fit your classifier and to plot the centroids. You should write your implementation above such that you don't need to modify the code in the next cell. As a sanity check, you should find that the 3rd centroid (for Staten Island) has a "year build" coordinate value of around 1976.8 (i.e., the rightmost column).

In [62]:
```
nc_classifier = NearestCentroidClassifier()  # Create a NearestCentroidClassifier object
nc_classifier.fit(nych_X, nych_y)            # Fit to the NYC training data

print(nc_classifier.centroids)
```

```
[array([  16.1489863 ,   25.07251963, 1926.94      ]), array([  14.60837771,   21.4446885 , 1935.29
]), array([  11.59781341,   19.20414033, 1976.83      ])]
```

In [64]:
```
X_test = nych_X[:10]
y_test = nych_y[:10]

y_pred = nc_classifier.predict(X_test)

print("Predicted labels:", y_pred)
print("True labels:", y_test)
```

```
Predicted labels: [0. 2. 0. 2. 2. 2. 0. 0. 2. 1.]
True labels: [1. 2. 0. 2. 1. 2. 0. 0. 1. 1.]
```

## Problem 2.2 (20 points): Evaluating the Nearest Centroids Classifier

Now that you've implemented the nearest centroid classifier, it is time to evaluate its performance.

- Write a function `compute_error_rate` that computes the error rate (fraction of misclassifications) of a model's predictions. That is, your function should take in an array of true labels y and an array of predicted labels `y_pred`, and

return the error rate of the predictions. You may use `numpy` to help you do this, but do not use `sklearn` or any other machine learning libraries.

- Write a function `compute_confusion_matrix` that computes the confusion matrix of a model's predictions. That is, your function should take in an array of true labels `y` and an array of predicted labels `y_pred`, and return the corresponding $C \times C$ confusion matrix as a numpy array, where $C$ is the number of classes. You may use `numpy` to help you do this, but do not use `sklearn` or any other machine learning libraries.
- Verify that your implementations of `NearestCentroidClassifier`, `compute_error_rate`, and `compute_confusion_matrix` are correct. To help you do this, you are given the functions `eval_sklearn_implementation` and `eval_my_implementation`. The function `eval_sklearn_implementation` will use the relevant `sklearn` implementations to compute the error rate and confusion matrix of a nearest centroid classifier. The function `eval_my_implementation` will do the same, but using your implementations. If your code is correct, the outputs of the two functions should be the same.

In [66]:
```
def compute_error_rate(y, y_pred):
    """
    Computes the error rate of an array of predictions.

    y: true labels; shape (n, ), where n is the number of datapoints.
    y_pred: predicted labels; shape (n, ), where n is the number of datapoints.

    Returns:
    error_rate: the error rate of y_pred compared to y; scalar expressed as a decimal (e.g. 0.5)
    """
    # Calculate the number of incorrect predictions
    incorrect = np.sum(y != y_pred)

    # Calculate the total number of predictions
    total = len(y)

    # Calculate the error rate (fraction of incorrect predictions)
    error_rate = incorrect / total

    return error_rate
```

In [67]:
```
def compute_confusion_matrix(y, y_pred):
    """
    Computes the confusion matrix of an array of predictions.

    y: true labels; shape (n, ), where n is the number of datapoints.
    y_pred: predicted labels; shape (n, ), where n is the number of datapoints.

    Returns:
    confusion_matrix: a numpy array corresponding to the confusion matrix from y and y_pred; shape (C, C),
        where C is the number of unique classes. The (i,j)th entry is the number of examples of class i
        that are classified as being from class j.
    """

    # Find the unique classes (C) in the data
    classes = np.unique(y)
    num_classes = len(classes)

    # Create an empty confusion matrix of shape (C, C)
    confusion_matrix = np.zeros((num_classes, num_classes), dtype=int)

    # Iterate through true and predicted labels and update the confusion matrix
    for true_label, predicted_label in zip(y, y_pred):
        # Find the indices of the true class and predicted class in the unique classes array
        true_index = np.where(classes == true_label)[0][0]
        predicted_index = np.where(classes == predicted_label)[0][0]

        # Increment the appropriate cell in the confusion matrix
        confusion_matrix[true_index, predicted_index] += 1

    return confusion_matrix
```

You can run the two code cells below to compare your answers to the implementations in `sklearn`. If your answers are correct, the outputs of these two functions should be the same. Do not modify the functions `eval_sklearn_implementation` and `eval_my_implementation`, but make sure that you read and understand this code.

In [69]:
```
################################################
### Results with the sklearn implementation ###

    # Make predictions on training and testing data
    y_pred = nearest_centroid.predict(X)

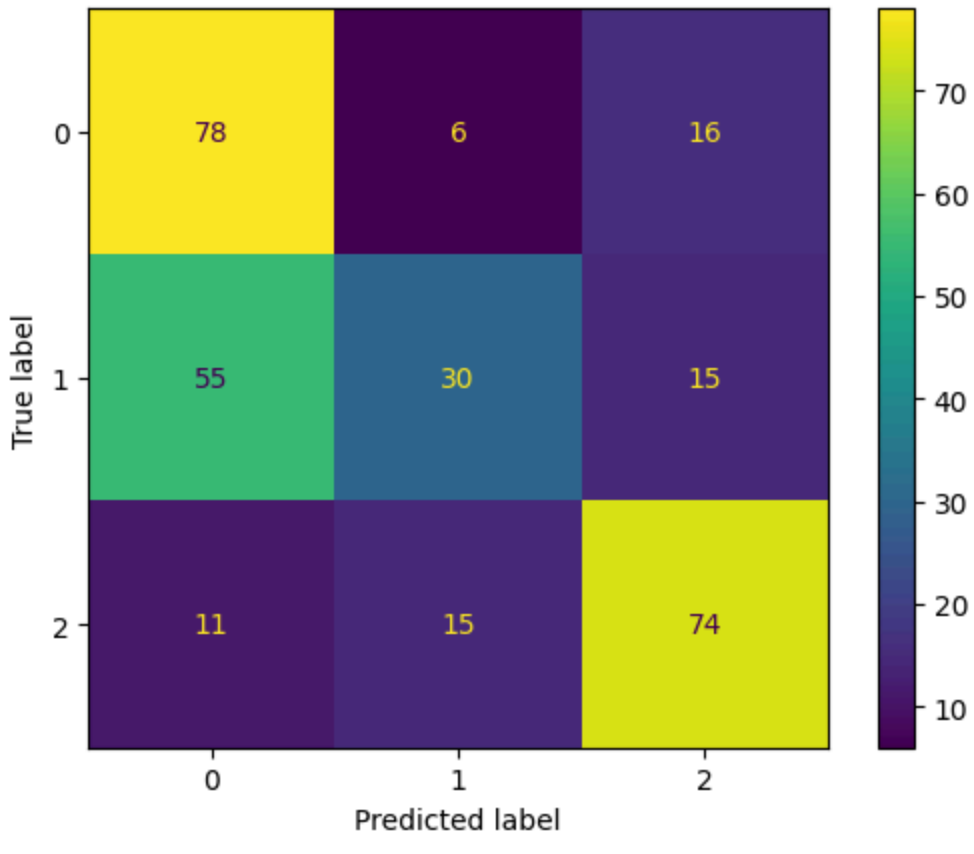
    # Evaluate accuracies using your function compute_accuracy
    err = zero_one_loss(y, y_pred)

    print(f'Your Results:')
    print(f'--- Error Rate (0/1): {err}')

    # Evaluate confusion matrix using your function compute_confusion_matrix
    cm = compute_confusion_matrix(y, y_pred)
    disp = ConfusionMatrixDisplay(confusion_matrix = cm)
    disp.plot();

# Call the function
eval_my_implementation(nych_X, nych_y)
```

```
Your Results:
--- Error Rate (0/1): 0.3933333333333333
```



---

## Problem 3: Decision Boundaries

For the final problem of this homework, you will visualize the decision function and decision boundary of your nearest centroid classifier on 2D data, and compare it to the similar but more flexible Gaussian Bayes classifier discussed in class. Code for drawing the decision function (which simply evaluates the prediction on a grid) and superimposing the data points is provided.

### Problem 3.1 (5 points): Visualize 2D Centroid Classifier

We will use only the first two features of the NYCH data set, to facilitate visualization.

In [75]:
```
# Import necessary modules
from sklearn.inspection import DecisionBoundaryDisplay
import matplotlib.pyplot as plt

# Some keyword arguments for making nice looking plots.
plot_kwargs = {'cmap': 'jet',     # another option: viridis
               'response_method': 'predict',
               'plot_method': 'pcolormesh',
               'shading': 'auto',
               'alpha': 0.5,
               'grid_resolution': 100}

# Create a figure
figure, axes = plt.subplots(1, 1, figsize=(4, 4))

# Instantiate your classifier (this can be sklearn's NearestCentroid or your own)
learner = NearestCentroidClassifier()  # or use sklearn's NearestCentroid()

### YOUR CODE STARTS HERE ###

# Get just the first two features of X (2D data for plotting)
nych_X2 = nych_X[:, :2]

# Fit "learner" to the nych 2-feature data
learner.fit(nych_X2, nych_y)

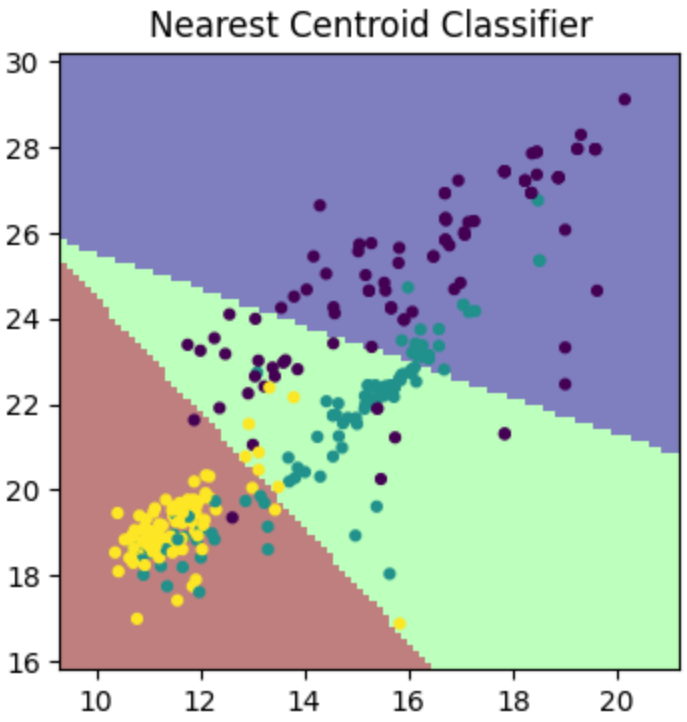
### YOUR CODE ENDS HERE ###

# Plot the decision boundary
DecisionBoundaryDisplay.from_estimator(learner, nych_X2, ax=axes, **plot_kwargs)

# Scatter plot of the data points
axes.scatter(nych_X2[:, 0], nych_X2[:, 1], c=nych_y, edgecolor=None, s=12)

# Set plot title
axes.set_title(f'Nearest Centroid Classifier')

# Show the plot
plt.show()
```



## Problem 3.2 (5 points): Visualize a 2D Gaussian Bayes Classifier

In class, we discussed building a Bayes classifier using an estimate of the class-conditional probabilities $p(X|Y=y)$, for example, a Gaussian distribution. It turns out this is relatively easy to implement and fairly similar to your Nearest Centroid classifier (in fact, Nearest Centroid is a special case of this model).

An implementation of a Gaussian Bayes classifier is provided:

In [76]:
```
class GaussianBayesClassifier:
    def __init__(self):
        """Initialize the Gaussian Bayes Classifier"""
        self.pY   = []         # class prior probabilities, p(Y=c)
        self.pXgY = []         # class-conditional probabilities, p(X|Y=c)
        self.classes_ = []     # list of possible class values

    def fit(self, X, y):
        """ Fits a Gaussian Bayes classifier with training features X and training labels y.
            X, y : (m,n) and (m,) arrays of training features and target class values
        """
        from sklearn.mixture import GaussianMixture
        self.classes_ = np.unique(y)         # Identify the class labels; then
        for c in self.classes_:              # for each class:
            self.pY.append(np.mean(y==c))    #   estimate p(Y=c) (a float)
            model_c = GaussianMixture(1)     #
            model_c.fit(X[y==c,:])           #   and a Gaussian for p(X|Y=c)
            self.pXgY.append(model_c)        #

    def predict(self, X):
        """ Makes predictions with the nearest centroid classifier on the features in X.
            X : (m,n) array of features for prediction
            Returns: y : (m,) numpy array of predicted labels
        """
        pXY = np.stack(tuple(np.exp(p.score_samples(X)) for p in self.pXgY)).T
        pXY *= np.array(self.pY).reshape(1,-1)         # evaluate p(X=x|Y=c) * p(Y=c)
        pYgX = pXY/pXY.sum(1,keepdims=True)            # normalize to p(Y=c|X=x) (not required)
        return self.classes_[np.argmax(pYgX, axis=1)]  # find the max index & return its class ID
```

Using this learner, evaluate the predictions and error rate on the training data, and plot the decision boundary. The code should be the same as your Nearest Centroid, but using the new learner object.

In [83]:
```
# Plot the decision boundary for your classifier

# Some keyword arguments for making nice looking plots.
plot_kwargs = {'cmap': 'jet',     # another option: viridis
               'response_method': 'predict',
               'plot_method': 'pcolormesh',
               'shading': 'auto',
               'alpha': 0.5,
               'grid_resolution': 100}

figure, axes = plt.subplots(1, 1, figsize=(4, 4))

learner = GaussianBayesClassifier()

### YOUR CODE STARTS HERE ###

# Get just the first two features of X (2D data for plotting)
nych_X2 = nych_X[:, :2]

# Fit "learner" to nych 2-feature data
learner.fit(nych_X2, nych_y)

# Use "learner" to predict on the same data used in training
gbc_y_pred = learner.predict(nych_X2)
```

```
### YOUR CODE ENDS HERE ###

# Evaluate the error
err = zero_one_loss(nych_y, gbc_y_pred)
print(f'Gaussian Bayes Error Rate (0/1): {err}')

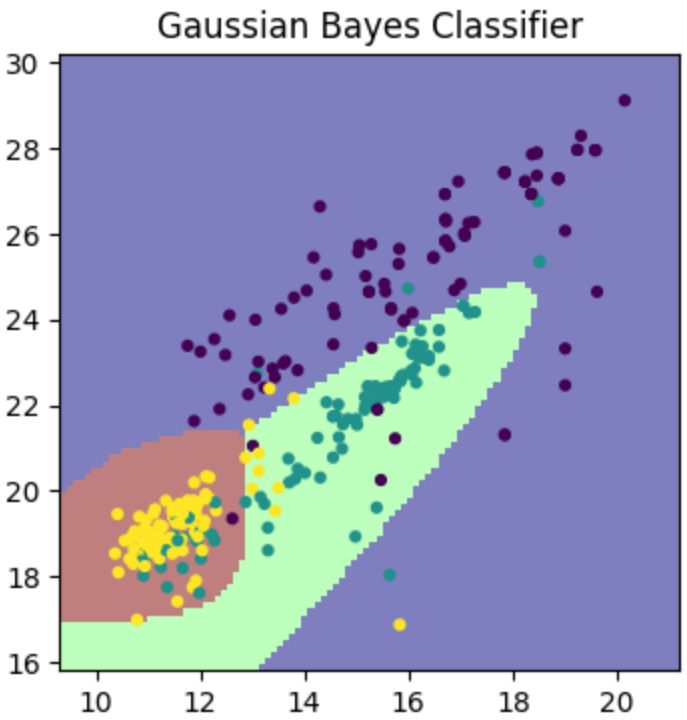
# Plot decision boundary
DecisionBoundaryDisplay.from_estimator(learner, nych_X2, ax=axes, **plot_kwargs)

# Scatter plot of the data points
axes.scatter(nych_X2[:, 0], nych_X2[:, 1], c=nych_y, edgecolor=None, s=12)

# Set plot title
axes.set_title(f'Gaussian Bayes Classifier')

# Show plot
plt.show()
```

```
Gaussian Bayes Error Rate (0/1): 0.15000000000000002
```



## Problem 3.3 (5 points): Analysis

Did the error increase or decrease? Why do you think this is?

The error decreased because the Gaussian Bayes Classifier found the remaining two features sufficient to model the class distributions effectively. Removing unnecessary or noisy features helped the classifier focus on the key patterns in the data, leading to more accurate predictions and improved performance.

---

## Statement of Collaboration (5 points)

It is **mandatory** to include a Statement of Collaboration in each submission, with respect to the guidelines below. Include the names of everyone involved in the discussions (especially in-person ones), and what was discussed.

All students are required to follow the academic honesty guidelines posted on the course website. For programming assignments, in particular, I encourage the students to organize (perhaps using EdD) to discuss the task descriptions, requirements, bugs in my code, and the relevant technical content before they start working on it. However, you should not discuss the specific solutions, and, as a guiding principle, you are not allowed to take anything written or drawn away from these discussions (i.e. no photographs of the blackboard, written notes, referring to EdD, etc.). Especially after you have started working on the assignment, try to restrict the discussion to EdD as much as possible, so that there is no doubt as to the extent of your collaboration.
